Detailed solution of the kinetic equation in the case of constant supply rate and Monod transformation kinetics

In case when the supply rate of the species Red is constant and its transformation follows the Monod scheme, the relevant kinetic equation takes the form:

$$\frac{dc_{\text{Red}}}{dt} = v_0 - \frac{k_{\text{max}}c_{\text{Red}}}{k_M + c_{\text{Red}}} \quad (\text{SI-1})$$

This is an autonomous differential equation. With the initial condition $c_{\text{Red}}(t = 0) = c_0$ its solution depends on the v_0 vs. k_{max} ratio. Reorganizing the right-hand side of (SI-1) leads to:

$$\frac{dc_{\text{Red}}}{dt} = \frac{v_0 k_M + (v_0 - k_{\text{max}})c_{\text{Red}}}{k_M + c_{\text{Red}}} \quad (\text{SI-2})$$

Rewriting (SI-2) in the following form:

$$\frac{k_M + c_{\text{Red}}}{v_0 k_M + (v_0 - k_{\text{max}})c_{\text{Red}}} dc_{\text{Red}} = dt \quad (\text{SI-3})$$

and introducing a new variable $z(t)$:

$$z(t) = v_0 k_M + (v_0 - k_{\text{max}})c_{\text{Red}}(t) \quad (\text{SI-4})$$

equation (SI-3) can be rearranged to get the form:

$$\frac{dz(t)}{(v_0 - k_{\max})^2} - \frac{k_M k_{\max}}{(v_0 - k_{\max})^2} \frac{dz(t)}{z(t)} = dt \quad (\text{SI-5})$$

Integrating (SI-5) with the initial condition $c_{\text{Red}}(t = 0) = c_0$ leads to a solution in an implicit form:

$$\begin{aligned} \frac{c_{\text{Red}}(t)}{v_0 - k_{\max}} - \frac{k_{\max} k_M}{(v_0 - k_{\max})^2} \ln[v_0 k_M + (v_0 - k_{\max}) \cdot c_{\text{Red}}(t)] = \\ = t + \frac{c_0}{v_0 - k_{\max}} - \frac{k_{\max} k_M}{(v_0 - k_{\max})^2} \ln[v_0 k_M + (v_0 - k_{\max}) \cdot c_0] \end{aligned} \quad (\text{SI-6})$$

Expressing $c_{\text{Red}}(t)$ in explicit form is not possible using elementary functions. To get the corresponding time evolution of E , it is therefore necessary to numerically solve (SI-6) for a given set of parameters, taking also into account an appropriate choice of physically meaningful branch consistent with initial conditions.
